UNIVERSITY COLLEGE OF ENGINEERING NAGERCOIL

(ANNA UNIVERSITY CONSTITUENT COLLEGE)

KONAM, NAGERCOIL – 629 004

Register No:

*Certified that, this is the bonafide record of work done by
Mr./Ms. of IV Semester
in Computer Science and Engineering of this college, in the
CS3461-Operating Systems Laboratory during academic year
2022-2023 in partial fulfillment of the requirements of the B.E
Degree course of the Anna University Chennai.*

Staff-in-charge

Head of the Department

This record is submitted for the University Practical Examination
held on

Internal Examiner

External Examiner

12		Write C programs to implement the various Page Replacement Algorithms	62	
13		Write C programs to Implement the various File Organization Techniques	70	
14		Implement the following File Allocation Strategies using C programs a) Sequential b) Linked c) Indexed	74	
15		Write C programs for the implementation of various disk scheduling algorithms	83	
16		Install any guest operating system like Linux using VMware.	92	

EX NO:01

INSTALLATION OF WINDOWS OPERATING SYSTEM

DATE:

AIM:

To Install Windows Operating System in Personal Computer.

PROCEDURE:

Step1: Check your device meets the Windows 10 system requirements. Below you'll find the minimum specs needed to run Windows 10, so check your device is capable:

CPU: 1GHz or faster processor

RAM: 1GB for Windows 10 32-bit or 2GB for Windows 10 64-bit

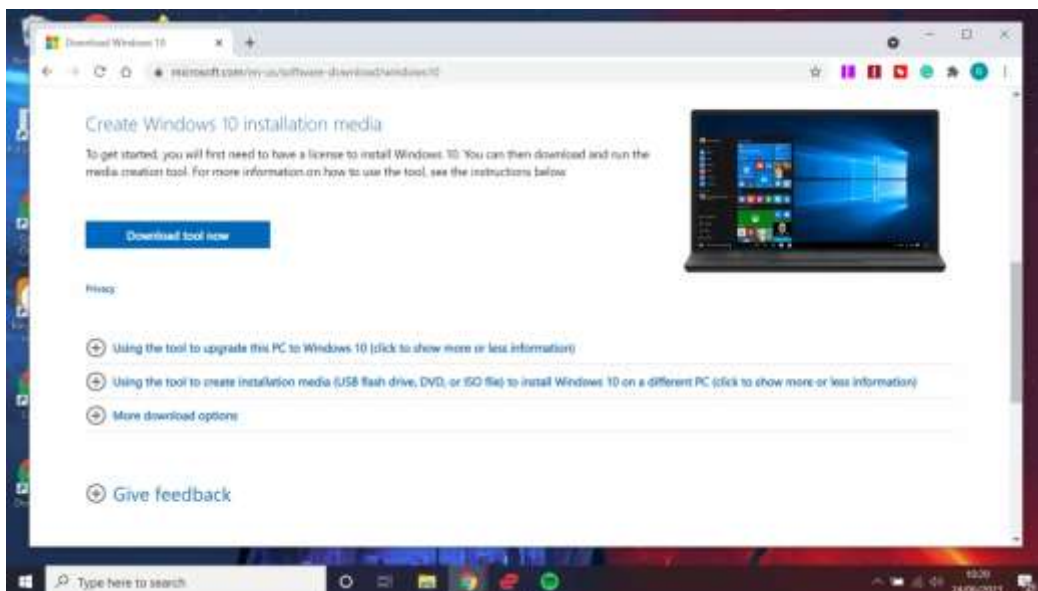

Storage: 32GB of space or more

GPU: DirectX 9 compatible or later with WDDM 1.0 driver

Display: 800x600 resolution or higher

If it meets the requirement, we can proceed to the next step.

Step2: Create USB installation media. Visit Microsoft's Windows 10 download page (opens in new tab) and select "Download tool now" under the "create Windows 10 installation media" section. Transfer the downloaded installer tool to a USB drive.

Step3: Run the installer tool. Open the installer tool by clicking on it. Accept Microsoft's terms, and then select **"Create installation media for another PC"** on the "What do you want to do?" page. After selecting which language, you want Windows 10 to run in, and which edition you want as well (32-bit or 64-bit), you'll be asked what type of media you want to use.

Installing from a USB drive is definitely the preferred option but you can also install from a CD or ISO file. Once you choose your device, the installer tool will download the required files and put them onto your drive.

Step4: Use your installation media. Insert your installation media into your device and then access **the computer's BIOS or UEFI**. These are the systems that allow you to control your computer's core hardware.

The process of accessing these systems is unique to each device, but the manufacturer's website should be able to give you a helping hand here. Generally, you'll need to **press the F2, F12 or Delete keys** as your computer boots up.

Step5: Change your computer's boot order. Once you have access to your computer's BIOS/UEFI you'll need to locate the settings for boot order. You need the Windows 10 installation tool to be higher up on the list than the device's current boot drive: this is the SSD or HDD that your existing OS is stored on. You should **move the drive with the installer files to the very top of the boot order menu**. Now, when you restart your device the Windows 10 installer should load up first.

Step6: Restart your device. Save your settings in the BIOS/UEFI and reboot your device.

Step7: Complete the installation. Your device should now load up the Windows 10 installation tool on restart. This will guide you through the rest of the installation process.

RESULT:

Thus, the installation of Windows Operating System is completed successfully.

EX NO:2a

ILLUSTRATE UNIX COMMANDS

DATE:

AIM:

To study and execute UNIX commands.

COMMANDS:

1. Date Command:

This command is used to display the current data and time.

Syntax:

```
$date  
$date +%ch
```

Options:

- a = Abbreviated weekday.
- A = Full weekday.
- b = Abbreviated month.
- B = Full month.
- c = Current day and time.
- C = Display the century as a decimal number.
- d = Day of the month.
- D = Day in „mm/dd/yy“ format
- h = Abbreviated month day.
- H = Display the hour.
- L = Day of the year.
- m = Month of the year.
- M = Minute.
- P = Display AM or PM
- S = Seconds
- T = HH:MM: SS format
- u = Week of the year.
- y = Display the year in 2 digits.
- Y = Display the full year.
- Z = Time zone.

OUTPUT:

```
balabharathy@DESKTOP-4678LTU:~$ date +%H:%M:%S  
19:58:09
```

2. Calendar Command:

This command is used to display the calendar of the year or a particular month of the calendar year.

Syntax:

- a.\$cal <year>
- b.\$cal <month> <year>

Here the first syntax gives the entire calendar for a given year & the second Syntax gives the calendar of the reserved months of that year.

OUTPUT:

```

```

3. Echo Command:

This command is used to print the arguments on the screen.

Syntax:

\$echo <text>

To have the output in different line, the following command can be used.

Syntax:

```
$echo "text  
>line2  
>line3"
```

OUTPUT:

```
balabharathy@DESKTOP-4678LTU:~$ echo "How  
> are  
> you?"  
How  
are  
you?
```

4. 'who' Command:

It is used to display who are the users connected to our computer currently.

Syntax: \$who -option's

```
$who -option's
```

Options:

H-Display the output with headers.

b-Display the last booting date or time or when the system was lately rebooted.

OUTPUT:

```
HEADER      2023-05-15 08:30      0.0.0.0  system boot
```

5. 'who am i' Command:

Display the details of the current working directory.

Syntax:

```
$who am i
```

OUTPUT:

```
$ who am i  
username pts/0      2023-05-15 10:30 (192.168.0.100)
```

6. 'tty' Command:

It will display the terminal name.

Syntax:

```
$tty
```

OUTPUT:

```
$ tty
/dev/pts/0
```

7. 'Binary' Calculator Command:

It will change the „\$ mode and in the new mode, arithmetic operations such as +, -, *, /, %, n, sqrt (), length (), =, etc can be performed. This command is used to go to the binary calculus mode.

Syntax:

```
$echo 'ibase=2; obase=2; <binary_expression>' | bc
```

OUTPUT:

```
balabharathy@DESKTOP-4678LTU:~$ echo 'ibase=2; obase=2; 1010 * 1101' | bc
10000010
```

8. 'CLEAR' Command:

It is used to clear the screen.

Syntax:

```
$clear
```

9. 'MAN' Command:

It helps us to know about the particular command and its options & working. It is like “help” command in Windows.

Syntax: \$man <command name>

```
$man <command name>
```

OUTPUT:

```
LS(1)                                User Commands                                LS(1)

NAME
  ls - list directory contents

SYNOPSIS
  ls [OPTION]... [FILE]...

DESCRIPTION
  List information about the FILES (the current directory by default).
  Sort entries alphabetically if none of -cftuvSUX nor --sort is speci-
  fied.

  Mandatory arguments to long options are mandatory for short options
  too.

  -a, --all
      do not ignore entries starting with .

  -A, --almost-all
      do not list implied . and ..

  --author
      with -l, print the author of each file

  -b, --escape
      print C-style escapes for nongraphic characters

Manual page ls(1) line 1 (press h for help or q to quit)
```

10. MANIPULATION Command:

It is used to manipulate the screen.

Syntax: \$tput <argument>

`$tput <argument>`

Arguments:

1. Clear – to clear the screen.
2. Longname – Display the complete name of the terminal.
3. smso – background becomes white and foreground becomes black colour.
4. rmso – background becomes black and foreground becomes white colour.

OUTPUT:

```
balabharathy@DESKTOP-4678LTU:~$ tput smso
balabharathy@DESKTOP-4678LTU:~$
```

11. LIST Command:

It is used to list all the contents in the current working directory.

Syntax:

`$ ls -options <arguments>`

If the command does not contain any argument means it is working in the Current directory.

Options:

- a- used to list all the files including the hidden files.
- c- list all the files columnwise.
- d- list all the directories.
- m- list the files separated by commas.
- p- list files include "/" to all the directories.

- r- list the files in reverse alphabetical order.
- f- list the files based on the list modification date.
- x-list in column wise sorted order.

OUTPUT:

```
ls -l -a /home/user/Documents

total 140
drwxr-xr-x  2 user user 4096 May 15 10:30 .
drwxr-xr-x 23 user user 4096 May 14 15:45 ..
-rw-r--r--  1 user user 52000 May 10 14:25 document1.txt
-rw-r--r--  1 user user 30000 May 10 14:30 document2.txt
drwxr-xr-x  2 user user 4096 May  9 17:12 subfolder
```

DIRECTORY RELATED COMMANDS:

1. Present Working Directory Command:

To print the complete path of the current working directory.

Syntax: \$pwd

```
$pwd
```

OUTPUT:

```
balabharathy@DESKTOP-4678LTU:~$ pwd
/home/balabharathy
```

2. MKDIR Command:

To create or make a new directory in a current directory.

Syntax:

```
$mkdir <directory name>
```

3. CD Command:

To change or move the directory to the mentioned directory.

Syntax:

```
$cd <directory name>
```

4. RMDIR Command:

To remove a directory in the current directory & not the current directory itself.

Syntax:

```
$rmdir <directory name>
```

FILE RELATED COMMANDS:

1. CREATE A FILE:

To create a new file in the current directory we use CAT command.

Syntax:

```
$cat > filename
```

The > symbol is the directory we use the cat command.

2. DISPLAY A FILE:

To display the content of the file mentioned we use the CAT command without the ">" operator.

Syntax:

```
$cat filename
```

RESULT:

Thus, various UNIX commands were studied and executed successfully.

EX NO:2b

SHELL PROGRAMMING

DATE:

AIM:

To write a shell programming in Ubuntu based on UNIX commands.

Shell script to find a number armstrong number or not:

ALGORITHM:

Step 1: Prompt the user to enter a number.

Step 2: Read and store the number in the variable number.

Step 3: Store the original value of number in the variable originalNumber.

Step 4: Calculate the number of digits in number using `${#number}` and store the result in numOfDigits.

Step 5: Initialize the variable sum to 0.

Step 6: Enter a loop that continues until number becomes 0:

- a. Extract the last digit of number using `$number % 10` and store it in digit.
- b. Calculate digit raised to the power of numOfDigits using `$digit**$numOfDigits`.
- c. Add the result to sum.
- d. Remove the last digit from number by dividing it by 10 using `$number / 10`.

Step 7: Check if sum is equal to originalNumber.

Step 8: If the condition is true, print that originalNumber is an Armstrong number.

Step 9: If the condition is false, print that originalNumber is not an Armstrong number.

PROGRAM:

```
#!/bin/bash
echo "Enter a number: "
read number
# Store the original number
originalNumber=$number
# Calculate the number of digits
numOfDigits=${#number}
# Initialize the sum
sum=0
# Iterate through each digit
while [ $number -gt 0 ]
do
    digit=$(( $number % 10 ))
    sum=$(( $sum + $digit**$numOfDigits ))
    number=$(( $number / 10 ))
done
```

```

done
# Check if the sum is equal to the original number
if [ $sum -eq $originalNumber ]
then
    echo "$originalNumber is an Armstrong number."
else
    echo "$originalNumber is not an Armstrong number."
fi

```

OUTPUT:

```

balabharathy@DESKTOP-4678LTU:~$ nano armstrong.sh
balabharathy@DESKTOP-4678LTU:~$ chmod +x armstrong.sh
balabharathy@DESKTOP-4678LTU:~$ ./armstrong.sh
Enter a number:
255
255 is not an Armstrong number.

```

Shell Script To Find the Greatest of Three Numbers

ALGORITHM:

- Step 1:** Prompt the user to enter the first number.
- Step 2:** Read and store the first number in the variable num1.
- Step 3:** Prompt the user to enter the second number.
- Step 4:** Read and store the second number in the variable num2.
- Step 5:** Prompt the user to enter the third number.
- Step 6:** Read and store the third number in the variable num3.
- Step 7:** Compare the values of the numbers using the following conditions:
 - a. If num1 is greater than both num2 and num3, then num1 is the greatest number.
 - b. If num2 is greater than both num1 and num3, then num2 is the greatest number.
 - c. Otherwise, num3 is the greatest number.
- Step 8:** Display the greatest number.

PROGRAM:

```

#!/bin/bash
echo "Enter the first number: "
read num1
echo "Enter the second number: "
read num2
echo "Enter the third number: "
read num3
if [ $num1 -gt $num2 ] && [ $num1 -gt $num3 ]
then
    echo "$num1 is the greatest."
elif [ $num2 -gt $num1 ] && [ $num2 -gt $num3 ]
then
    echo "$num2 is the greatest."
else

```

```
echo "$num3 is the greatest."  
fi
```

OUTPUT:

```
balabharathy@DESKTOP-4678LTU:~$ ./greatest.sh  
Enter the first number:  
34  
Enter the second number:  
67  
Enter the third number:  
34  
67 is the greatest.
```

Shell Script to Find the sum of two numbers

ALGORITHM:

- Step 1:** Prompt the user to enter the first number.
- Step 2:** Read and store the first number in the variable num1.
- Step 3:** Prompt the user to enter the second number.
- Step 4:** Read and store the second number in the variable num2.
- Step 5:** Calculate the sum of num1 and num2 by adding them together.
- Step 6:** Store the sum in the variable sum.
- Step 7:** Display the sum of the two numbers along with the original numbers.

PROGRAM:

```
#!/bin/bash  
echo "Enter the first number: "  
read num1  
echo "Enter the second number: "  
read num2  
sum=$((num1 + num2))  
echo "The sum of $num1 and $num2 is: $sum"
```

OUTPUT:

```
balabharathy@DESKTOP-4678LTU:~$ nano sum.sh  
balabharathy@DESKTOP-4678LTU:~$ chmod +x sum.sh  
balabharathy@DESKTOP-4678LTU:~$ ./sum.sh  
Enter the first number:  
55  
Enter the second number:  
45  
The sum of 55 and 45 is: 100
```

Shell Script to calculate the average of three numbers

ALGORITHM:

- Step 1:** Prompt the user to enter the first number.
- Step 2:** Read and store the first number in the variable num1.
- Step 3:** Prompt the user to enter the second number.
- Step 4:** Read and store the second number in the variable num2.
- Step 5:** Prompt the user to enter the third number.

Step 6: Read and store the third number in the variable num3.

Step 7: Calculate the sum of the three numbers by adding them together.

Step 8: Divide the sum by 3 to calculate the average.

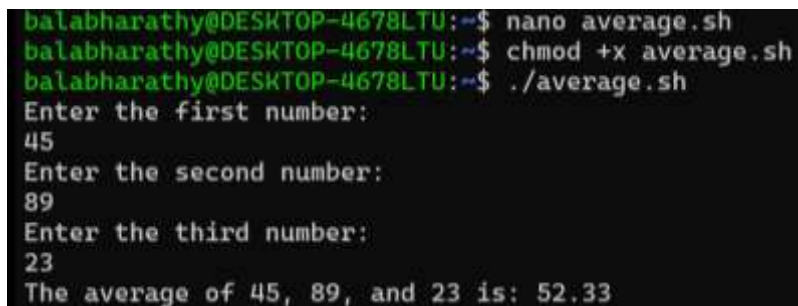

Step 9: Store the average in the variable average.

Step 10: Display the average of the three numbers along with the original numbers.

PROGRAM:

```
#!/bin/bash
echo "Enter the first number: "
read num1
echo "Enter the second number: "
read num2
echo "Enter the third number: "
read num3
sum=$((num1 + num2 + num3))
average=$(echo "scale=2; $sum / 3" | bc)
echo "The average of $num1, $num2, and $num3 is: $average"
```

OUTPUT:

```
balabharathy@DESKTOP-4678LTU:~$ nano average.sh
balabharathy@DESKTOP-4678LTU:~$ chmod +x average.sh
balabharathy@DESKTOP-4678LTU:~$ ./average.sh
Enter the first number:
45
Enter the second number:
89
Enter the third number:
23
The average of 45, 89, and 23 is: 52.33
```

RESULT:

Thus, the shell programming based on UNIX commands is verified and executed successfully.

EX NO:03

**PROCESS MANAGEMENT USING SYSTEM CALLS:
FORK, EXIT, GETPID, WAIT, CLOSE**

DATE:

a) PROGRAM USING SYSTEM CALL: FORK ()

AIM:

To write the program to create a Child Process using system call **fork ()**.

ALGORITHM:

Step 1: Declare the variable pid.

Step 2: Get the pid value using system call fork ().

Step 3: If pid value is less than zero then print as "Fork failed".

Step 4: Else if pid value is equal to zero include the new process in the system"s Fil. using execlp system call.

Step 5: Else if pid is greater than zero then it is the parent process and it waits till the child completes using the system call wait ()

Step 6: Then print "Child complete"

PROGRAM:

```
#include <stdio.h>
#include <stdlib.h>
#include <sys/wait.h>
#include <unistd.h>

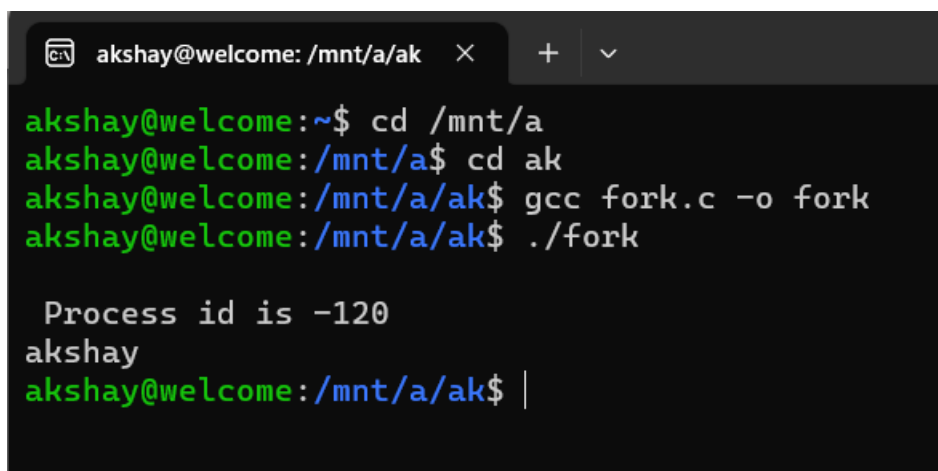

void main(int argc, char *arg[]) {
    int pid;
    pid = fork(); // create a new process
    if (pid < 0) {
        printf("fork failed");
        exit(1);
    } else if (pid == 0) { // child process
        execlp("whoami", "ls", NULL); // replace child process code with whoami command
        exit(0); // exit child process
    } else { // parent process
        printf("\n Process id is -%d\n", getpid()); // print parent process ID
        wait(NULL); // wait for child process to finish
        exit(0); // exit parent process
    }
}
```

System call used:

1.fork ():

The fork () system call is a fundamental operating system call in Unix-like operating systems, including Linux, macOS, and FreeBSD. It is used to create a new process, which is called a child process. The fork () system call creates a new process by duplicating the calling process, which becomes the parent process of the new child process. The new child process is an exact copy of the parent process, except that it has its own unique process ID (PID) and parent process ID (PPID).

OUTPUT:

```
akshay@welcome: /mnt/a/ak × + v
akshay@welcome:~$ cd /mnt/a
akshay@welcome:/mnt/a$ cd ak
akshay@welcome:/mnt/a/ak$ gcc fork.c -o fork
akshay@welcome:/mnt/a/ak$ ./fork

Process id is -120
akshay
akshay@welcome:/mnt/a/ak$ |
```

b) PROGRAM USING SYSTEM CALL: EXIT ()

AIM:

To write the program to implement the system calls **exit ()**.

ALGORITHM:

- Step 1:** Include the necessary header files: `stdio.h`, `stdlib.h`, and `unistd.h`.
- Step 2:** Declare a variable of type `pid_t` to store the process ID returned by `fork ()`.
- Step 3:** Call `fork ()` to create a child process. If `fork ()` returns -1, an error has occurred, so print an error message using `perror()` and exit the program with a failure status using `exit()`.
- Step 4:** If the process is the child process, print its process ID using `getpid()`, a message indicating that it is running and another message indicating that it is exiting, then exit the process with a success status using `exit()`.
- Step 5:** Print a message with parent process ID, wait for child process to finish using `wait()` with `NULL` argument, and print message for child process finishing.
- Step 6:** Exit the program with a success status using `return 0`.

PROGRAM:

```
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>
#include <sys/wait.h>

int main() {
    pid_t pid;
    pid = fork();
    if (pid == -1) {
        perror("fork error");
        exit(EXIT_FAILURE);
    } else if (pid == 0) {
        printf("Child process is running with process ID: %d\n", getpid());
        printf("Child process is exiting...\n");
        exit(EXIT_SUCCESS);
    } else {
        printf("Parent process is running with process ID: %d\n", getpid());
        printf("Waiting for child process to finish...\n");
        wait(NULL);
        printf("Child process has finished.\n");
    }

    return 0;
}
```

System call used:

1.exit ():

The System call exit () is used to terminate a process.

OUTPUT:

```
akshay@welcome:/mnt/a/ak$ gcc exit.c -o exit
akshay@welcome:/mnt/a/ak$ ./exit
Parent process is running with process ID: 45
Waiting for child process to finish...
Child process is running with process ID: 46
Child process is exiting...
Child process has finished.
akshay@welcome:/mnt/a/ak$ |
```

c) PROGRAM USING SYSTEM CALLS: GETPID ()

AIM:

To write the program to implement the system call **getpid()**.

ALGORITHM:

Step 1: Declare a variable of type `pid_t` to store the process ID returned by `fork ()`.

Step 2: Call `fork ()` to create a child process. If `fork ()` returns -1, an error has occurred, so print an error message using `perror()` and exit the program with a failure status using `exit()`.

Step 3: If the process is the child process, print a message indicating that the child process is running with its process ID using `getpid()`.

Step 4: If the process is the parent process, print a message indicating that the parent process is running with its process ID using `getpid()`.

Step 5: Exit the program with a success status using `return 0`.

PROGRAM:

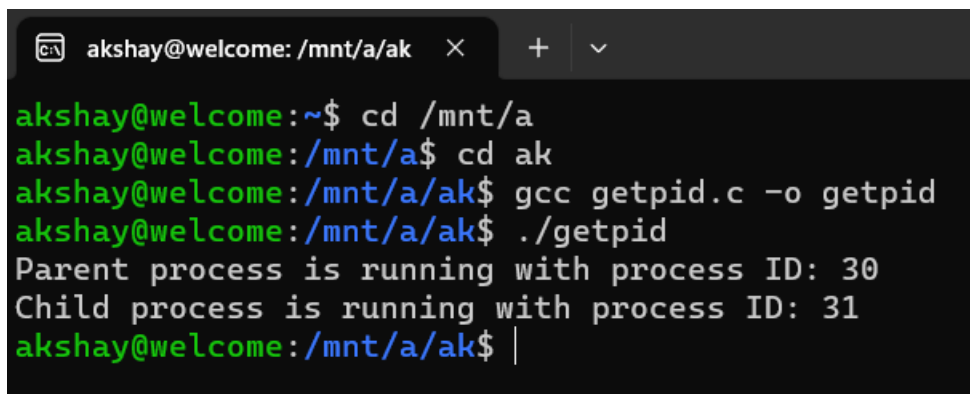

```
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>
int main() {
    pid_t pid;
    pid = fork();
    if (pid == -1) {
        perror("fork error");
        exit(EXIT_FAILURE);
    } else if (pid == 0) {
        printf("Child process is running with process ID: %d\n", getpid());
    } else {
        printf("Parent process is running with process ID: %d\n", getpid());
    }
    return 0;
}
```

System call used:

1.getpid ():

‘`getpid()`’ is a system call in Unix and Unix-like operating systems that returns the process ID (PID) of the calling process.

OUTPUT:

```
akshay@welcome: /mnt/a/ak × + v
akshay@welcome:~$ cd /mnt/a
akshay@welcome:/mnt/a$ cd ak
akshay@welcome:/mnt/a/ak$ gcc getpid.c -o getpid
akshay@welcome:/mnt/a/ak$ ./getpid
Parent process is running with process ID: 30
Child process is running with process ID: 31
akshay@welcome:/mnt/a/ak$ |
```

d) PROGRAM USING SYSTEM CALLS: WAIT ()

AIM:

To write the program to implement the system call **wait ()**.

ALGORITHM:

- Step 1:** Declare variables pid, cpid, and status of types pid_t and int.
- Step 2:** Call fork () to create a child process, and handle the error case where fork () returns -1.
- Step 3:** In the child process, print a message indicating that it is a child process, sleep for 5 seconds, and then exit with a success status.
- Step 4:** In the parent process, print a message indicating that it is a parent process, and wait for the child process to terminate using wait () and store the child process ID and exit status in cpid and status variables respectively.
- Step 5:** Check if the child process terminated normally using WIFEXITED (status), and if so, print a message indicating the child process ID and exit status. Otherwise, print a message indicating that the child process terminated abnormally.
- Step 6:** Exit the program with a success status.

PROGRAM:

```
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>
#include <sys/wait.h>

int main() {
    pid_t pid, cpid;
    int status;

    pid = fork();
```

```

if (pid == -1) {
    perror("fork error");
    exit(EXIT_FAILURE);
} else if (pid == 0) {
    printf("Child process\n");
    sleep(5);
    exit(EXIT_SUCCESS);
} else {
    printf("Parent process\n");
    cpid = wait(&status);
    if (WIFEXITED(status)) {
        printf("Child process %d terminated with status %d\n", cpid,
WEXITSTATUS(status));
    } else {
        printf("Child process %d terminated abnormally\n", cpid);
    }
}

return 0;
}

```

System call used:

1.wait ():

In computing, wait () is a system call that suspends the calling process until one of its child processes terminates. It also provides information about the child process that terminated, such as its exit status.

OUTPUT:

```

akshay@welcome:/mnt/a/ak$ gcc wait.c -o wait
akshay@welcome:/mnt/a/ak$ ./wait
Parent process
Child process
Child process 40 terminated with status 0
akshay@welcome:/mnt/a/ak$ |

```

e) PROGRAM USING SYSTEM CALL: CLOSE ()

AIM:

To write the program to implement the system call close ().

ALGORITHM:

Step 1: Declare an integer variable `fd` for file descriptor

Step 2: Open a file named `test.txt` with the `open ()` system call using the flags `O_WRONLY`, `O_CREAT`, and `O_TRUNC`, and permissions `S_IRUSR` and `S_IWUSR`. Store the file descriptor returned by the `open ()` call in `fd`

Step 3: Check if `fd` is equal to `-1`, if it is, print an error message using `perror()`, and exit the program with a failure status using `exit()`

Step 4: Print a message indicating that the file has been opened with the file descriptor `fd`

Step 5: Write the string `"Hello, world! \n"` to the file using the `write ()` system call, passing `fd` as the file descriptor and `14` as the number of bytes to write. Check if the return value is `-1`, if it is, print an error message using `perror()`, and exit the program with a failure status using `exit()`

Step 6: Close the file using the `close ()` system call, passing `fd` as the file descriptor. Check if the return value is `-1`, if it is, print an error message using `perror()`, and exit the program with a failure status using `exit()`

Step 7: Print a message indicating that the file has been closed

Step 8: Exit the program with a success status using `exit ()`

PROGRAM:

```
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>
#include <fcntl.h>
int main () {
    int fd;
    // Open a file for writing
    fd = open("test.txt", O_WRONLY | O_CREAT | O_TRUNC, S_IRUSR | S_IWUSR);
    if (fd == -1) {
        perror("open error");
        exit(EXIT_FAILURE);
    }
    printf("File opened with file descriptor %d\n", fd);
    // Write some data to the file
    if (write(fd, "Hello, world!\n", 14) == -1) {
```

```
    perror("write error");
    exit(EXIT_FAILURE);
}
// Close the file
if (close(fd) == -1) {
    perror("close error");
    exit(EXIT_FAILURE);
}

printf("File closed\n");

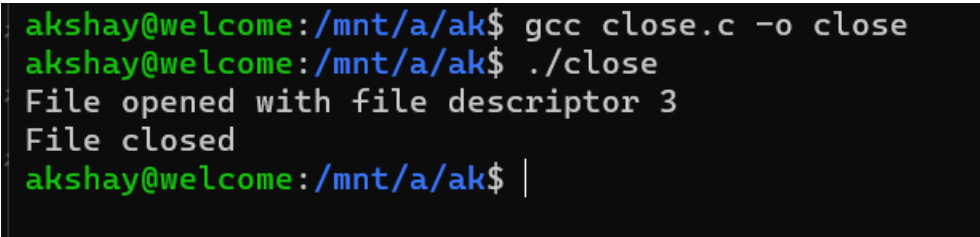

return 0;
}
```

System call used:

1.close ():

In operating systems, close () is a system call that is used to release a file descriptor and free the associated kernel resources. It returns 0 on success and -1 on failure, setting errno to indicate the cause of the error.

OUTPUT:

```
akshay@welcome:/mnt/a/ak$ gcc close.c -o close
akshay@welcome:/mnt/a/ak$ ./close
File opened with file descriptor 3
File closed
akshay@welcome:/mnt/a/ak$ |
```

RESULT:

Thus, process management using system calls: fork (), exit (), getpid(), wait() and close() was executed successfully.

EX NO: 04

DATE:

WRITE A C PROGRAM TO IMPLEMENT THE VARIOUS CPU SCHEDULING ALGORITHM

AIM:

To write a C program to implement the various CPU Scheduling algorithms.

a) FIRST COME FIRST SERVE (FCFS) SCHEDULING

ALGORITHM:

Step 1: Start the process

Step 2: Accept the number of processes in the ready Queue

Step 3: For each process in the ready Q, assign the process name and the burst time

Step 4: Set the waiting of the first process as 0 and its burst time as its turnaround time

Step 5: for each process in the Ready Q calculate

Step 5.1: Waiting time (n) = waiting time (n-1) + Burst time (n-1)

Step 5.2: Turnaround time (n) = waiting time(n) + Burst time(n)

Step 6: Calculate

Step 6.1: Average waiting time = Total waiting Time / Number of process

Step 6.2: Average Turnaround time = Total Turnaround Time / Number of process

Step 7: Stop the process

PROGRAM:

```
#include<stdio.h>
#include<conio.h>
int main()
{
int bt[20], wt[20], tat[20], i, n;
float wtavg, tatavg;
clrscr();
printf("\nEnter the number of processes -- ");
scanf("%d", &n);
for(i=0;i<n;i++)
{
printf("\nEnter Burst Time for Process %d -- ", i);
scanf("%d", &bt[i]);
}
wt[0] = wtavg = 0;
tat[0] = tatavg = bt[0];
for(i=1;i<n;i++)
```

```

{
wt[i] = wt[i-1] +bt[i-1];
tat[i] = tat[i-1] +bt[i];
wtavg = wtavg + wt[i];
tatavg = tatavg + tat[i];
}
printf("\t PROCESS \tBURST TIME \t WAITING TIME\t TURNAROUND TIME\n");
for(i=0;i<n;i++)
printf("\n\t P%d \t\t %d \t\t %d \t\t %d", i, bt[i], wt[i], tat[i]);
printf("\nAverage Waiting Time -- %f", wtavg/n);
printf("\nAverage Turnaround Time -- %f", tatavg/n);
getch();}

```

OUTPUT:

```

Enter the number of processes -- 3
Enter Burst Time for Process 0 -- 24
Enter Burst Time for Process 1 -- 3
Enter Burst Time for Process 2 -- 3
PROCESS          BURST TIME          WAITING TIME          TURNAROUND TIME
P0                24                0                24
P1                3                24                27
P2                3                27                30
Average Waiting Time -- 17.000000
Average Turnaround Time -- 27.000000

```

b) SHORTEST JOB FIRST(SJF) SCHEDULING

ALGORITHM:

Step 1: Start the process

Step 2: Accept the number of processes in the ready Queue

Step 3: For each process in the ready Q, assign the process id and accept the CPU burst time

Step 4: Start the Ready Q according the shortest Burst time by sorting according to lowest to highest burst time.

Step 5: Set the waiting time of the first process as 0 and its turnaround time as its burst time.

Step 6: Sort the processes names based on their Burt time

Step 7: For each process in the ready queue, calculate

Step 7.1: Waiting time(n) = waiting time (n-1) + Burst time (n-1)

Step 7.2: Turnaround time (n) = waiting time(n)+Burst time(n)

Step7.3: Average waiting time = Total waiting Time / Number of process

Step 7.4: Average Turnaround time = Total Turnaround Time / Number of process

Step 8: Stop the process

PROGRAM:

```
#include<stdio.h>
#include<conio.h>
main()
{
int p[20], bt[20], wt[20], tat[20], i, k, n, temp; float wtavg,
tatavg;
clrscr();
printf("\nEnter the number of processes -- ");
scanf("%d", &n);
for(i=0;i<n;i++)
{
p[i]=i;
printf("Enter Burst Time for Process %d -- ", i);
scanf("%d", &bt[i]);
}
for(i=0;i<n;i++)
for(k=i+1;k<n;k++)
if(bt[i]>bt[k])
{
temp=bt[i];
bt[i]=bt[k];
bt[k]=temp;
temp=p[i];
p[i]=p[k];
p[k]=temp;
}
wt[0] = wtavg = 0;
tat[0] = tatavg = bt[0]; for(i=1;i<n;i++)
{
wt[i] = wt[i-1] +bt[i-1];
tat[i] = tat[i-1] +bt[i];
wtavg = wtavg + wt[i];
tatavg = tatavg + tat[i];
}
printf("\n\tPROCESS \tBURST TIME \t WAITING TIME\t TURNAROUND TIME\n");
for(i=0;i<n;i++)
printf("\n\t P%d \t\t %d \t\t %d \t\t %d", p[i], bt[i], wt[i], tat[i]);
printf("\nAverage Waiting Time -- %f", wtavg/n);
printf("\nAverage Turnaround Time -- %f", tatavg/n);
getch();
}
```

OUTPUT:

```
Enter the number of processes -- 4
Enter Burst Time for Process 0 -- 6
Enter Burst Time for Process 1 -- 8
Enter Burst Time for Process 2 -- 7
Enter Burst Time for Process 3 -- 3

PROCESS          BURST TIME          WAITING TIME          TURNAROUND TIME

P2                7                9               16
P1                8               16               24
Average Waiting Time -- 7.000000
Average Turnaround Time -- 13.000000
```

c) ROUND ROBIN SCHEDULING

ALGORITHM:

Step 1: Start the process

Step 2: Accept the number of processes in the ready Queue and time quantum

Step 3: For each process in the ready Q, assign the process id and accept the CPU burst time

Step 4: Calculate the no. of time slices for each process where No. of time slice for process (n) = burst time process (n)/time slice

Step 5: If the burst time is less than the time slice then the no. of time slices =1.

Step 6: Consider the ready queue is a circular Q, calculate

Step 6.1: Waiting time for process (n) = waiting time of process(n-1) + burst time of process (n-1) + the time difference in getting the CPU from process(n-1)

Step 6.2: Turnaround time for process(n) = waiting time of process(n) + burst time of process(n)+ the time difference in getting CPU from process(n).

Step 6.3: Average waiting time = Total waiting Time / Number of process

Step 6.4: Average Turnaround time = Total Turnaround Time / Number of process

Step 7: Stop the process

PROGRAM:

```
#include<stdio.h>
main()
{
int i,j,n,bu[10],wa[10],tat[10],t,ct[10],max;
float awt=0,att=0,temp=0;
clrscr();
printf("Enter the no of processes -- ");
```

```

scanf("%d",&n);
for(i=0;i<n;i++)
{
printf("\nEnter Burst Time for process %d -- ", i+1);
scanf("%d",&bu[i]);
ct[i]=bu[i];
}
printf("\nEnter the size of time slice -- ");
scanf("%d",&t);
max=bu[0];
for(i=1;i<n;i++)
if(max<bu[i])
max=bu[i];
for(j=0;j<(max/t)+1;j++)
for(i=0;i<n;i++)
if(bu[i]!=0)
if(bu[i]<=t)
{
tat[i]=temp+bu[i];
temp=temp+bu[i];
bu[i]=0;
}
else
{
bu[i]=bu[i]-t;
temp=temp+t;
}
for(i=0;i<n;i++)
{
wa[i]=tat[i]-
ct[i]; att+=tat[i];
awt+=wa[i];
}
printf("\nThe Average Turnaround time is -- %f",att/n);
printf("\nThe Average Waiting time is -- %f",awt/n);
printf("\n\tPROCESS\t BURST TIME \t WAITING TIME\tTURNAROUND TIME\n");
for(i=0;i<n;i++)
printf("\t%d \t %d \t\t %d \t\t %d \n",i+1,ct[i],wa[i],tat[i]);
getch();
}

```

OUTPUT:

```
Enter the no of processes -- 3
Enter Burst Time for process 1 -- 5
Enter Burst Time for process 2 -- 6
Enter Burst Time for process 3 -- 24
Enter the size of time slice -- 3

The Average Turnaround time is -- 20.000000
The Average Waiting time is -- 8.333333
PROCESS  BURST TIME    WAITING TIME    TURNAROUND TIME
1         5             6              11
2         6             8              14
3        24            11              35
```

d) PRIORITY SCHEDULING

ALGORITHM:

Step 1: Start the process

Step 2: Accept the number of processes in the ready Queue

Step 3: For each process in the ready Q, assign the process id and accept the CPU burst time

Step 4: Sort the ready queue according to the priority number.

Step 5: Set the waiting of the first process as 0 and its burst time as its turnaround time

Step 6: Arrange the processes based on process priority

Step 7: For each process in the Ready Q calculate

Step 8: for each process in the Ready Q calculate

Step 8.1: Waiting time(n)= waiting time (n-1) + Burst time (n-1)

Step 8.2: Turnaround time (n)= waiting time(n)+Burst time(n)

Step 8.3: Average waiting time = Total waiting Time / Number of process

Step 8.4: Average Turnaround time = Total Turnaround Time / Number of process

Step 9: Print the results in an order.

Step 10: Stop the process

PROGRAM:

```
#include<stdio.h>
main()
{
int p[20],bt[20],pri[20], wt[20],tat[20],i, k, n, temp; float wtavg,
tatavg;
clrscr();
printf("Enter the number of processes --- ");
scanf("%d",&n);
for(i=0;i<n;i++)
{
```

```

p[i] = i;
printf("Enter the Burst Time & Priority of Process %d --- ",i); scanf("%d
%d",&bt[i], &pri[i]);
}
for(i=0;i<n;i++)
for(k=i+1;k<n;k++)
if(pri[i] > pri[k])
{
temp=p[i];
p[i]=p[k];
p[k]=temp;
temp=bt[i];
bt[i]=bt[k];
bt[k]=temp;
temp=pri[i];
pri[i]=pri[k];
pri[k]=temp;
}
wtavg = wt[0] = 0;
tatavg = tat[0] = bt[0];
for(i=1;i<n;i++)
{
wt[i] = wt[i-1] + bt[i-1];
tat[i] = tat[i-1] + bt[i];
wtavg = wtavg + wt[i];
tatavg = tatavg + tat[i];
}
printf("\nPROCESS\t\tPRIORITY\tBURST TIME\tWAITING TIME\tTURNAROUND
TIME");
for(i=0;i<n;i++)
printf("\n%d \t\t %d \t\t %d \t\t %d \t\t %d ",p[i],pri[i],bt[i],wt[i],tat[i]);
printf("\nAverage Waiting Time is --- %f",wtavg/n); printf("\nAverage
Turnaround Time is --- %f",tatavg/n);
getch();
}

```

OUTPUT:

```
Enter the number of processes --- 5

Average Waiting Time is --- 4.600000
Average Turnaround Time is --- 6.600000
```

e) SHORTEST REMAINING TIME SCHEDULING

ALGORITHM:

Step 1: Start

Step 2: Declare and initialize necessary variables and arrays.

Step 3: Input the number of processes (n) from the user.

Step 4: Iterate over each process from 0 to n-1 and input the arrival time and burst time.

Step 5: Set the remaining time for each process to the corresponding burst time.

Step 6: Print the table header for the turnaround time and waiting time.

Step 7: Set a flag process smallest to 9 indicating no valid process available initially.

Step 8: Run a loop until all processes are completed (remain! = n).

Step 9: Find the process with the smallest remaining time among the arrived processes.

Step 10: Decrement the remaining time for the selected process.

Step 11: If the remaining time of the selected process becomes 0, mark it as completed, calculate its end time, print the process details.

Step 12: Increment the time variable.

Step 13: After completing the loop, calculate and print the average waiting time and average turnaround time.

Step 14: Stop

PROGRAM:

```
#include<stdio.h>
int main()
{
    int at[10],bt[10],rt[10],endTime,i,smallest;
    int remain=0,n,time,sum_wait=0,sum_turnaround=0;
    printf("\n\tEnter no of Processes : ");
    scanf("%d",&n);
    for(i=0;i<n;i++)
    {
        printf("\n\tEnter arrival time for Process P%d : ",i+1);
        scanf("%d",&at[i]);
        printf("\n\tEnter burst time for Process P%d : ",i+1);
        scanf("%d",&bt[i]);
        rt[i]=bt[i];
    }
    printf("\n\tProcess\t|Turnaround Time| Waiting Time\n\n");
    rt[9]=9999;
    for(time=0;remain!=n;time++)
    {
        smallest=9;
        for(i=0;i<n;i++)
        {
            if(at[i]<=time && rt[i]<rt[smallest] && rt[i]>0)
            {
                smallest=i;
            }
        }
        rt[smallest]--;
        if(rt[smallest]==0)
        {
            remain++;
            endTime=time+1;
            printf("\n\tP[%d]\t|\t%d\t|\t%d",smallest+1,endTime-at[smallest],endTime-bt[smallest]-
                                                         at[smallest]);

            sum_wait+=endTime-bt[smallest]-at[smallest];
            sum_turnaround+=endTime-at[smallest];
        }
    }
    printf("\n\n\tAverage waiting time = %f\n",sum_wait*1.0/n);
    printf("\n\tAverage Turnaround time = %f",sum_turnaround*1.0/5);
```

```

getch();
}

```

OUTPUT:

```

Enter no of Processes : 3
Enter arrival time for Process P1 : 101

Average waiting time = 0.000000
Average Turnaround time = 1.000000

```

f) MULTILEVEL QUEUE SCHEDULING

ALGORITHM:

- Step 1:** Start
- Step 2:** Initialize arrays for process ID (p), burst time (bt), system/user process (su), waiting time (wt), and turnaround time (tat).
- Step 3:** Read the number of processes (n) from the user.
- Step 4:** Using a loop, read the burst time and system/user process for each process from the user and store it in the corresponding array.
- Step 5:** Using nested loops, sort the processes in ascending order based on them system/user process (su), so that system processes come before user processes.
- Step 6:** Initialize waiting time (wt) and turnaround time (tat) for the first process to 0.
- Step 7:** Using a loop, calculate the waiting time (wt) and turnaround time (tat) for each process based on the burst time and waiting time of the previous process.
- Step 8:** Calculate the average waiting time and average turnaround time using the formula:
sum of all waiting/turnaround times divided by the number of processes.
- Step 9:** Print the process ID, system/user process, burst time, waiting time, and turnaround time for each process using a loop.
- Step 10:** Print the average waiting time and average turnaround time.
- Step 11:** Stop

PROGRAM:

```
#include<stdio.h>
int main()
{
int p[20],bt[20], su[20], wt[20],tat[20],i, k, n, temp;
float wtavg, tatavg;
printf("Enter the number of processes:");
scanf("%d",&n);
for(i=0;i<n;i++)
{
p[i] = i;
printf("Enter the Burst Time of Process%d:", i);
scanf("%d",&bt[i]);
printf("System/User Process (0/1) ? ");
scanf("%d", &su[i]);

**ILLUSTARTE THE INTER PROCESS
COMMUNICATION STRATEGY**

AIM:

To demonstrate communication between process using shared memory.

ALGORITHM:

SERVER:

Step1: Initialize size of shared memory shmsize to 27.

Step2: Initialize key to 2013 (some random value).

Step 3: Create a shared memory segment using shmget with key & IPC_CREAT as parameter.

a. If shared memory identifier shmid is -1, then stop.

Step 4: Display shmid.

Step 5: Attach server process to the shared memory using shmat with shmid as parameter.

a. If pointer to the shared memory is not obtained, then stop.

Step 6: Clear contents of the shared region using memset function.

Step 7: Write a–z onto the shared memory.

Step 8: Wait till client reads the shared memory contents

Step 9: Detach process from the shared memory using shmdt system call.

Step10: Remove shared memory from the system using shmctl with IPC_RMID argument

CLIENT:

Step1: Initialize size of shared memory shmsize to 27.

Step2: Initialize key to 2013 (same value as in server).

Step3: Obtain access to the same shared memory segment using same key.

a. If obtained then display the shmid else print "Server not started"

Step4: Attach client process to the shared memory using shmat with shmid as parameter.

a. If pointer to the shared memory is not obtained, then stop.

Step5: Read contents of shared memory and print it.

Step6: After reading, modify the first character of shared memory to '*'

PROGRAM:

Server:/* Shared memory server - shms.c */

```
#include <stdio.h>
#include <stdlib.h>
#include <sys/un.h>
#include <sys/types.h>
#include <sys/ipc.h>
#include <sys/shm.h>
#define shmsize 27
main()
{
    char c;
    int shmid;
    key_t key = 2013;
    char *shm, *s;
    if ((shmid = shmget(key, shmsize, IPC_CREAT|0666)) < 0)
    {
        perror("shmget");
        exit(1);
    }
    printf("Shared memory id : %d\n", shmid);
    if ((shm = shmat(shmid, NULL, 0)) == (char *) -1)
    {
        perror("shmat");
        exit(1);
    }
    memset(shm, 0, shmsize);
    s = shm;
    printf("Writing (a-z) onto shared memory\n");
    for (c = 'a'; c <= 'z'; c++)
        *s++ = c;
    *s = '\0';
    while (*shm != '*');
    printf("Client finished reading\n");
    if(shmdt(shm) != 0)
        fprintf(stderr, "Could not close memory segment.\n");
    shmctl(shmid, IPC_RMID, 0);
}
```

Client:/* Shared memory client - shmc.c */

```
#include <stdio.h>
#include <stdlib.h>
#include <sys/types.h>
#include <sys/ipc.h>
#include <sys/shm.h>
#define shmsize 27
main()
{
```

```

int shmid;
key_t key = 2013;
char *shm, *s;
if ((shmid = shmget(key, shmsize, 0666)) < 0)
{
printf("Server not started\n");
exit(1);
}
else
printf("Accessing shared memory id : %d\n",shmid);if ((shm = shmat(shmid, NULL, 0)) ==
(char *) -1)
{
perror("shmat");
exit(1);
}
printf("Shared memory contents:\n");
for (s = shm; *s != '\0'; s++)
putchar(*s);
putchar('\n');
*shm = '*';
}

```

OUTPUT:

Server Output:

```

Shared memory id : 12345
Writing (a-z) onto shared memory
Client finished reading

```

Client Output:

```

Accessing shared memory id : 12345
Shared memory contents:
abcdefghijklmnopqrstuvwxyz

```

RESULT:

Thus, to demonstrate communication between process using shared memory was executed successfully.

EX NO:06

MUTUAL EXCLUSION BY SEMAPHORE

DATE:

AIM:

To write a C program to implement the producer and consumer problem using semaphores

ALGORITHM:

Step 1: Start the program.

Step 2: Declare the required variables.

Step 3: Initialize the buffer size and get maximum item you want to produce.

Step 4: Get the option, which you want to do either producer, consumer or exit from the operation.

Step 5: If you select the producer, check the buffer size if it is full the producer should not produce the item or otherwise produce the item and increase the value buffer size.

Step 6: If you select the consumer, check the buffer size if it is empty the consumer should not consume the item or otherwise consume the item and decrease the value of buffer size.

Step 7: If you select exit come out of the program.

Step 8: Stop the program.

PROGRAM:

```
#include<stdio.h>
int mutex=1,full=0,empty=3,x=0;
main()
{
int n;
void producer();
void consumer();
int wait(int);
int signal(int);
printf("\n 1.producer\n2.consumer\n3.exit\n");
while(1)
```

```

{
printf(" \nenter ur choice");
scanf("%d",&n);
switch(n)
{
case 1:
if((mutex==1)&&(empty!=0))
producer();
else
printf("buffer is full\n");
break;
case 2:
if((mutex==1)&&(full!=0))
consumer();
else
printf("buffer is empty");
break;
case 3:
exit(0);
break;
}
}
}
int wait(int s)
{
return(--s);
}
int signal(int s)
{
return (++s);
}
void producer()
{
mutex=wait(mutex);
full=signal(full);
empty=wait(empty);
x++;
printf("\n producer produces the items %d",x);
mutex=signal(mutex);
}
void consumer()
{
mutex=wait(mutex);
full=wait(full);
empty=signal(empty);
printf("\n consumer consumes the item %d",x);
x--;
mutex=signal(mutex);
}

```

```
}
```

OUTPUT:

```
1.producer
2.consumer
3.exit

enter ur choice1

producer produces the items 1
enter ur choice1

producer produces the items 2
enter ur choice1

producer produces the items 3
enter ur choice2

consumer consumes the item 3
enter ur choice2

consumer consumes the item 2
enter ur choice2

consumer consumes the item 1
enter ur choice2
buffer is empty
enter ur choice3

...Program finished with exit code 0
Press ENTER to exit console.
```

RESULT:

Thus, the C program to implement the Producer and Consumer using semaphore was executed successfully.

EX NO:07

AVOIDING DEADLOCK USING BANKER'S ALGORITHM

DATE:

AIM:

To write a C program to implement banker's algorithm for deadlock avoidance.

ALGORITHM:

Step 1: Start the program.

Step 2: Declare the memory for the process.

Step 3: Read the number of processes, resources, allocation matrix and available matrix.

Step 4: Compare each and every process using the banker's algorithm.

Step 5: If the process is in safe state, then it is not a deadlock process otherwise it is a deadlock process

Step 6: produce the result of state of process

Step 7: Stop the program

PROGRAM:

```
#include<stdio.h>
#include<conio.h>
int max[100][100];
int alloc[100][100];
int need[100][100];
int avail[100];
int n,r;
void input();
void show();
void cal();
int main()
{
    int i,j;
    printf("***** Banker's Algorithm *****\n");
    input();
    show();
    cal();
    getch();
    return 0;
}
void input()
```

```

{
int i,j;
printf("Enter the no of Processes\t");
scanf("%d",&n);
printf("Enter the no of resources instances\t");
scanf("%d",&r);
printf("Enter the Max Matrix\n");
for(i=0;i<n;i++) {

P2       2 0 0      3 2 2
P3       3 0 2      9 0 2
P4       2 1 1      2 2 2
P5       0 0 2      4 3 3

P1->P4->P3->P5->P2->
The system is in safe state
```

RESULT:

Thus, a C program to implement banker's algorithm for deadlock avoidance is executed successfully.

EX NO:08

DATE:

**WRITE A C PROGRAM TO IMPLEMENT DEADLOCK
DETECTION ALGORITHM**

AIM:

To determine whether the process and their request for resources are in a deadlock state.

ALGORITHM:

Step 1: Declare and initialize the necessary variables and arrays for the program.

Step 2: Input the user's number of processes and resource instances.

Step 3: Input the Max matrix, Allocation matrix, and Available Resources matrix from the user.

Step 4: Show the input matrices and available resources matrix on the console.

Step 5: Calculate the Need matrix by subtracting the Allocation matrix from the Max matrix.

Step 6: Initialize the Finish array to all 0s.

Step 7: While there is still a process that is not finished:

- a) Look for a process that has not finished and whose resource needs are less than or equal to the available resources.
- b) If such a process is found, mark it as finished, add its allocated resources back to the available resources, and continue the loop.
- c) If no such process is found, the system is in deadlock. Print out the processes that are deadlocked and terminate the program.

Step 8: If all processes are finished, print out that no deadlock occurred and terminate the program.

PROGRAM:

```
#include <stdio.h>
int max[100][100];
int alloc[100][100];
int need[100][100];
int avail[100];
int n, r;
void input();
void show();
void cal();
int main()
{
    int j,i;
```

```

printf("*****Deadlock Detection Algorithm*****\n");
input();
show();
cal();
return 0;
}
void input()
{
    int i,j;
    printf("Enter the no of Processes\t");
    scanf("%d",&n);
    printf("Enter the no of resource instances\t");
    scanf("%d",&r);
    printf("Enter the Max Matrix\n");
    for(i=0;i<n;i++)
        for(j=0;j<r;j++)
            scanf("%d",&max[i][j]);
    printf("Enter the Allocation Matrix\n");
    for(i=0;i<n;i++)
        for(j=0;j<r;j++)
            scanf("%d",&alloc[i][j]);
    printf("Enter the Available Resources\n");
    for(j=0;j<r;j++)
        scanf("%d",&avail[j]);
}
void show()
{
    int i,j;
    printf("Process\t Allocation\t Max\t Available\t\n");
    for(i=0;i<n;i++)
    {

EX NO:09

WRITE C PROGRAM TO IMPLEMENT THREADING

DATE:

AIM:

To implement threading in a C program.

ALGORITHM:

Step 1: Define a constant "NUM_THREADS" to specify the number of threads to be created.

Step 2: Define a function "print_hello" that takes a thread ID as an argument and prints a greeting message.

Step 3: In the main function, declare an array of "pthread_t" structures to represent the threads and an integer variable "rc" to store the return value of the "pthread_create" function.

Step 4: Using a loop, create "NUM_THREADS" threads, passing the "print_hello" function and the thread ID as arguments to each thread.

Step 5: Check if the "pthread_create" function returns any error, if so, print an error message and exit the program.

Step 6: Call the "pthread_exit" function to terminate the main thread and wait for all other threads to finish their execution.

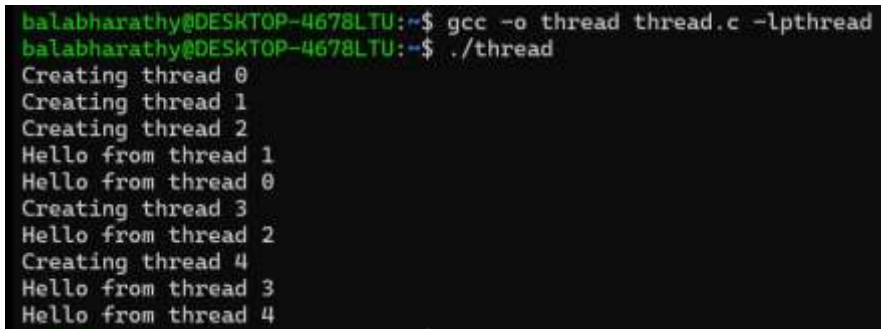

Step 7: Return 0 to indicate successful execution of the program.

PROGRAM:

```
#include <stdio.h>
#include <stdlib.h>
#include <pthread.h>
#define NUM_THREADS 5
void *print_hello(void *thread_id)
{
    long tid = (long)thread_id;
    printf("Hello from thread %ld\n", tid);
    pthread_exit(NULL);
}
int main()
{
    pthread_t threads[NUM_THREADS];
    int rc;
    long t;
    for (t = 0; t < NUM_THREADS; t++) {
        printf("Creating thread %ld\n", t);
```

```
rc = pthread_create(&threads[t], NULL, print_hello, (void *)t);
if (rc) {
    printf("ERROR; return code from pthread_create() is %d\n", rc);
    exit(EXIT_FAILURE);
}
}
pthread_exit(NULL);
return 0;
}
```

OUTPUT:

```
balabharathy@DESKTOP-4678LTU:~$ gcc -o thread thread.c -lpthread
balabharathy@DESKTOP-4678LTU:~$ ./thread
Creating thread 0
Creating thread 1
Creating thread 2
Hello from thread 1
Hello from thread 0
Creating thread 3
Hello from thread 2
Creating thread 4
Hello from thread 3
Hello from thread 4
```

RESULT:

Thus, implementing threading in a C program is verified and executed successfully.

IMPLEMENT THE PAGING TECHNIQUE USING C PROGRAM

AIM:

To implement the Paging Technique using C program.

ALGORITHM:

Step 1: Declare necessary variables, including size, n, pgno, pagetable, ra, ofs, and frameno.

Step 2: Read in the process size from the user.

Step 3: Calculate the number of pages required for the process by dividing the size by the page size (4KB).

Step 4: Round up the number of pages to the nearest integer using the ceil function from the math.h library.

Step 5: Read in the relative address in hexadecimal format from the user.

Step 6: Calculate the page number and offset from the relative address.

Step 7: Display the page number and the current contents of the page table.

Step 8: Get the frame number corresponding to the current page number from the page table.

Step 9: Calculate the physical address by concatenating the frame number and the offset.

Step 10: Display the physical address.

PROGRAM:

```
#include<stdio.h>
#include<math.h>
void main() {
    int size, n, pgno, pagetable[3] = {5, 6, 7}, i, j, frameno;
    double ml;
    int ra = 0, ofs;
    // Read process size
    printf("Enter process size (in KB of max 12KB): ");
    scanf("%d", &size);
    // Calculate number of pages required
    ml = size / 4;
    n = ceil(ml);
    printf("Total No. of pages: %d\n", n);
    // Read relative address in hexadecimal format
    printf("\nEnter relative address (in hexa): ");
    scanf("%x", &ra);
    // Calculate page number and offset
    pgno = ra / 1000;
    ofs = ra % 1000;
```

```

printf("Page no = %d\n", pgno);
// Display page table
printf("Page table:\n");
for(i = 0; i < n; i++) {
    printf("%d[%d]\n", i, pagetable[i]);
}
// Get frame number from page table
framenno = pagetable[pgno];
// Calculate physical address and display it
printf("\nPhysical address: %d%d\n", framenno, ofs);
}

```

OUTPUT:

```

balabharathy@DESKTOP-4678LTU:~$ gcc page.c -o page -lm
balabharathy@DESKTOP-4678LTU:~$ ./page
Enter process size(in KB of max 12KB):12
Total No.of pages: 3
Enter relative address (in hexa)
2643
page no=9
page table
0[5]
1[6]
2[7]
Physical address: 0795balabharathy@DESKTOP-4678LTU:~$ .

```

RESULT:

Thus, the C program to implement paging technique is verified and executed successfully.

MEMORY ALLOCATION METHODS

DATE:

AIM:

To write a C program to implement the following memory allocation methods.

- a. FIRST FIT**
- b. WORST FIT**
- c. BEST FIT**

a) FIRST FIT:

ALGORITHM:

Step 1: Start.

Step 2: Define the max as 25.

Step 3: Declare the variable frag[max],b[max],f[max],i,j,nb,nf,temp, highest=0, bf[max],ff[max].

Step 4: Get the number of blocks,files,size of the blocks using for loop.

Step 5: In for loop check bf[j]!=1, if so temp=b[j]-f[i]

Step 6: Check highest

Step 7: Stop.

PROGRAM:

```
#include<stdio.h>
#include <conio.h>
#define max 25
void main()
{
int frag[max],b[max],f[max],i,j,nb,nf,temp,highest=0;
static int bf[max],ff[max];
clrscr();
printf("\n\tMemory Management Scheme -First Fit");
printf("\nEnter the number of blocks:");
scanf("%d",&nb);
printf("Enter the number of files:");
scanf("%d",&nf);
printf("\nEnter the size of the blocks:-\n");
for(i=1;i<=nb;i++)
{
```

```

printf("Block %d:",i);
scanf("%d",&b[i]);
}
printf("Enter the size of the files :-\n");
for(i=1;i<=nf;i++)
{
printf("File %d:",i);
scanf("%d",&f[i]);
}
for(i=1;i<=nf;i++)
{
for(j=1;j<=nb;j++)
{
if(bf[j]!=1)
{
temp=b[j]-f[i];
if(temp>=0)
if(highest<temp)
{
ff[i]=j;
highest=temp;
}
}
}
}
frag[i]=highest;
bf[ff[i]]=1;
highest=0;
}
printf("\nFile_no:\tFile_size :\tBlock_no:\tBlock_size:\tFragement");
for(i=1;i<=nf;i++)
printf("\n%d\t\t%d\t\t%d\t\t%d\t\t%d",i,f[i],ff[i],b[ff[i]],frag[i]);
getch();
}

```

OUTPUT:

```

Memory management scheme-First fit
Enter the number of blocks:3
Enter the number of files:2

Enter the size of the blocks:
Block 1:5
Block 2:2
Block 3:7
Enter the size of the files:
File 1:1
File 2:4

File no:      File_size:      Block_no:      Block_size:      Fragment
1             1             3             7             6
2             4             1             5             1_

```

b) WORST FIT:

ALGORITHM:

Step 1: Start

Step 2: Define the max as 25.

Step 3: Declare the variable frag[max], b[max], f[max], i,j,nb,nf,temp, highest=0, bf[max],ff[max].

Step 4: Get the number of blocks,files,size of the blocks using for loop.

Step 5: In for loop check bf[j]!=1, if so temp=b[j]-f[i]

Step 6: Check temp>=0, if so assign ff[i]=j breaks the for loop.

Step 7: Assign frag[i]=temp,bf[ff[i]]=1;

Step 8: Repeat step 4 to step 6.

Step 9: Print file no,size,block no,size and fragment.

Step 10: Stop the program.

PROGRAM:

```
#include<stdio.h>
#include<conio.h>
#define max 25
void main()
{
int frag[max],b[max],f[max],i,j,nb,nf,temp;
static int bf[max],ff[max];
clrscr();
printf("\n\tMemory Management Scheme - Worst Fit");
printf("\nEnter the number of blocks:");
scanf("%d",&nb);
printf("Enter the number of files:");
scanf("%d",&nf);
printf("\nEnter the size of the blocks:-\n");
for(i=1;i<=nb;i++)
{
printf("Block %d:",i);
scanf("%d",&b[i]);
}
printf("Enter the size of the files :-\n");
for(i=1;i<=nf;i++)
{
printf("File %d:",i);
```

```

scanf("%d",&f[i]);
}
for(i=1;i<=nf;i++)
{
    for(j=1;j<=nb;j++)
    {
        if(bf[j]!=1)
        {
            temp=b[j]-f[i];
            if(temp>=0)
            {
                ff[i]=j;
                break;
            }
        }
    }
    frag[i]=temp;
    bf[ff[i]]=1;
}
printf("\nFile_no:\tFile_size :\tBlock_no:\tBlock_size:\tFragement");
for(i=1;i<=nf;i++)
printf("\n%d\t%d\t%d\t%d\t%d",i,f[i],ff[i],b[ff[i]],frag[i]);
getch();
}

```

OUTPUT:

```

RESULT:

Thus, the C program to implement the memory allocation methods best fit, worst fit, first fit was executed successfully.

EX NO:12

PAGE REPLACEMENT ALGORITHMS

DATE:

AIM:

To write a C program to implement the following page replacement algorithms.

1. **First in First out.**
2. **Optimal page replacement.**
3. **Least recently used.**

1) FIRST IN FIRST OUT:

ALGORITHM:

Step 1: Start the process.

Step 2: Declare the size with respect to page length.

Step 3: Check the need of replacement from the page to memory.

Step 4: Check the need of replacement from old page to new page in memory.

Step 5: Form a queue to hold all pages.

Step 6: Insert the page require memory into the queue.

Step 7: Check for bad replacement and page fault.

Step 8: Get the number of processes to be inserted.

Step 9: Display the values.

Step 10: Stop the process.

PROGRAM:

```
#include<stdio.h>
int main()
{
int i,j,n,a[50],frame[10],no,k,avail,count=0;
printf("\n ENTER THE NUMBER OF PAGES:\n");
scanf("%d",&n);
printf("\n ENTER THE PAGE NUMBER :\n");
for(i=1;i<=n;i++)
scanf("%d",&a[i]);
printf("\n ENTER THE NUMBER OF FRAMES :");
```

```

scanf("%d",&no);
for(i=0;i<no;i++)
    frame[i]= -1;
    j=0;
    printf("\tref string\t page frames\n");
for(i=1;i<=n;i++)
{
    printf("%d\t\t",a[i]);
    avail=0;
    for(k=0;k<no;k++)
if(frame[k]==a[i])
        avail=1;
    if (avail==0)
    {
        frame[j]=a[i];
        j=(j+1)%no;
        count++;
        for(k=0;k<no;k++)
            printf("%d\t",frame[k]);
    }

    printf("\n");
}

printf("Page Fault Is %d",count);
return 0;
}

```

OUTPUT:

```

Administrator: Command Prompt
ENTER THE NUMBER OF PAGES:

EX NO:14 a

**IMPLEMENT THE FOLLOWING FILE ALLOCATION
STRATEGIES USING C PROGRAMS
SEQUENTIAL**

DATE:

AIM:

To write a C program to implement sequential file allocation.

ALGORITHM:

Step 1: Start the program.

Step 2: Get the number of memory partition and their sizes.

Step 3: Get the number of processes and values of block size for each process.

Step 4: First fit algorithm searches all the entire memory block until a hole which is big enough is encountered. It allocates that memory block for the requesting process.

Step 5: Best-fit algorithm searches the memory blocks for the smallest hole which can be allocated to requesting process and allocates it.

Step 6: Worst fit algorithm searches the memory blocks for the largest hole and allocates it to the process.

Step 7: Analyses all the three memory management techniques and display the best algorithm which utilizes the memory resources effectively and efficiently.

Step 8: Stop the program.

PROGRAM:

```
#include <stdio.h>
#include <stdlib.h>

void main()
{
    int f[50], i, st, len, j, c, k, count = 0;
```

```

for (i = 0; i < 50; i++)
    f[i] = 0;

printf("Files Allocated are:\n");

x:
count = 0;
printf("Enter starting block and length of files: ");
scanf("%d %d", &st, &len);

for (k = st; k < (st + len); k++)
{
    if (f[k] == 0)
        count++;
}

if (len == count)
{
    for (j = st; j < (st + len); j++)
    {
        if (f[j] == 0)
        {
            f[j] = 1;
            printf("%d\t%d\n", j, f[j]);
        }
    }
    if (j != (st + len - 1))
        printf("The file is allocated to the disk\n");
}
else
{
    printf("The file is not allocated\n");
}

printf("Do you want to enter more files? (Yes - 1 / No - 0): ");
scanf("%d", &c);

if (c == 1)
    goto x;

getch();
}

```

OUTPUT:

```
Files Allocated are:  
Enter starting block and length of files: 2 5  
2 1  
3 1  
4 1  
5 1  
6 1  
The file is allocated to the disk  
Do you want to enter more files? (Yes - 1 / No - 0): 1  
Enter starting block and length of files: 10 3  
10 1  
11 1  
12 1  
The file is allocated to the disk  
Do you want to enter more files? (Yes - 1 / No - 0): 0
```

RESULT:

Thus, a C program to implement sequential file allocation was verified and executed successfully.

EX NO:14 b

LINKED FILE ALLOCATION

DATE:

AIM:

To write a C program to implement linked file allocation.

ALGORITHM:

Step 1: Start the program

Step 2: Create a queue to hold all pages in memory

Step 3: When the page is required replace the page at the head of the queue

Step 4: Now the new page is inserted at the tail of the queue

Step 5: Create a stack

Step 6: When the page fault occurs replace page present at the bottom of the stack

Step 7: Stop the allocation.

PROGRAM:

```
#include<stdio.h>
#include<conio.h>
#include<stdlib.h>
void main()
{
int f[50], p,i, st, len, j, c, k, a;
clrscr();
for(i=0;i<50;i++)
f[i]=0;
printf("Enter how many blocks already allocated: ");
scanf("%d",&p);
printf("Enter blocks already allocated: ");
for(i=0;i<p;i++)
{
scanf("%d",&a);
f[a]=1;
}
x: printf("Enter index starting block and length: ");
scanf("%d%d", &st,&len);
k=len;
if(f[st]==0)
{
for(j=st;j<(st+k);j++)
{
if(f[j]==0)
{
f[j]=1;
printf("%d----->%d\n",j,f[j]);
}
}
else
{
printf("%d Block is already allocated \n",j);
k++;
}
}
else
printf("%d starting block is already allocated \n",st);
printf("Do you want to enter more file(Yes - 1/No - 0)");
scanf("%d", &c);
if(c==1)
goto x;
else
exit(0);
getch();
}
```

OUTPUT:

```
Enter how many blocks already allocated: 3
Enter blocks already allocated: 2 5 7
Enter index starting block and length: 3 4
3----->1
4----->1
5 Block is already allocated
6----->1
Do you want to enter more file (Yes - 1 / No - 0): 1
Enter index starting block and length: 8 2
8----->1
9----->1
Do you want to enter more file (Yes - 1 / No - 0): 0
```

RESULT:

Thus, a C program to implement linked file allocation was verified and executed successfully.

EX NO:14 c

INDEXED FILE ALLOCATION

DATE:

AIM:

To write a C program to implement indexed file allocation.

ALGORITHM:

Step 1: Start

Step 2: Let n be the size of the buffer

Step 3: check if there are any producer

Step 4: if yes check whether the buffer is full

Step 5: If no the producer item is stored in the buffer

Step 6: If the buffer is full the producer has to wait

Step 7: Check there is any consumer.If yes check whether the buffer is empty

Step 8: If no the consumer consumes them from the buffer

Step 9: If the buffer is empty, the consumer has to wait.

Step 10: Repeat checking for the producer and consumer till required

Step 11: Terminate the process.

PROGRAM:

```
#include<stdio.h>
#include<conio.h>
#include<stdlib.h>
void main()
{
int f[50], index[50],i, n, st, len, j, c, k, ind,count=0;
clrscr();
for(i=0;i<50;i++)
f[i]=0;
x:printf("Enter the index block: ");
scanf("%d",&ind);
if(f[ind]!=1)
{
printf("Enter no of blocks needed and no of files for the index %d on the disk : \n", ind);
scanf("%d",&n);
}
else
{
printf("%d index is already allocated \n",ind);
goto x;
}
y: count=0;
for(i=0;i<n;i++)
{
scanf("%d", &index[i]);
if(f[index[i]]==0)
count++;
}
if(count==n)
{
for(j=0;j<n;j++)
f[index[j]]=1;
printf("Allocated\n");
printf("File Indexed\n");
for(k=0;k<n;k++)
printf("%d----->%d : %d\n",ind,index[k],f[index[k]]);
}
else
{
printf("File in the index is already allocated \n");
printf("Enter another file indexed");
goto y;
}
printf("Do you want to enter more file(Yes - 1/No - 0)");
scanf("%d", &c);
if(c==1)
goto x;
else
```

```
exit(0);
getch();
}
```

OUTPUT:

```
Enter the index block: 1
Enter no of blocks needed and no of files for the index 1 on the disk:
3
Enter the block numbers for each file:
2
3
4
Do you want to enter more files? (Yes - 1/No - 0): 1
Enter the index block: 2
Enter no of blocks needed and no of files for the index 2 on the disk:
2
Enter the block numbers for each file:
5
6
Do you want to enter more files? (Yes - 1/No - 0): 0
```

```
Allocated
File Indexed
1----->2 : 1
1----->3 : 1
1----->4 : 1
Do you want to enter more files? (Yes - 1/No - 0):
Allocated
File Indexed
2----->5 : 1
2----->6 : 1
Do you want to enter more files? (Yes - 1/No - 0):
```

RESULT:

Thus, a C program to implement indexed file allocation was verified and executed successfully.

EX NO:15

**WRITE C PROGRAMS FOR THE IMPLEMENTATION
OF VARIOUS DISK SCHEDULING ALGORITHMS**

DATE:

AIM:

To write C programs for the implementation of various disk scheduling algorithms.

ALGORITHM:

Step 1: Start

Step 2: Define function FCFS (First-come, First-Served)

Step 2.1: Traverse the disk request array in the order of arrival.

Step 2.2: For each request, calculate the seek time as the absolute difference between the current request and previous request

Step 2.3: Update the current head position to the current request

Step 2.4: Repeat until all requests are processed

Step 2.5: Display the sequence of disk access and the total seek time.

Step 3: Define function SSTF (Shortest Seek Time First)

Step 3.1: Initialize a visited array to keep track of visited disk requests

Step 3.2: Traverse the disk request array

Step 3.3: Find the request with the shortest seek time for the current head position that has not been visited yet

Step 3.4: Mark the selected request as visited

Step 3.5: Calculate the seek time as the absolute difference between the current request and the previous request

Step 3.6: Update the current head position to the current request

Step 3.7: Display the sequence of disk access and the total seek time

Step 4: Define the function SCAN

Step 4.1: Sort the disk request array in ascending order

Step 4.2: Find the index where the head is located

Step 4.3: Traverse the disk request array from the head position towards higher cylinder number

Step 4.5: Calculate the seek time as the absolute difference between the current request and the previous request

Step 4.6: Update the current head position to the current request

Step 4.7: Repeat until reaching the end of the disk

Step 4.8: Jump to the lower end of the disk

Step 4.9: Traverse the disk request array from the lower end towards the start

Step 4.10: Calculate the seek time as the absolute difference between the current request and the previous request

Step 4.11: Update the current head position to the current request

Step 4.12: Repeat until reaching the start of the disk

Step 4.13: Display the sequence of disk access and the total seek time

Step 5: Display the function C-SCAN (Circular SCAN)

Step 5.1: Sort the disk request array in ascending order

Step 5.2: Find the index where the head is located

Step 5.3: Traverse the disk request array from head position towards higher cylinder numbers

Step 5.4: Calculate the seek time as the absolute difference between the current request and the previous request

Step 5.5: Update the current head position to the current request

Step 5.6: Repeat until reaching the end of the disk

Step 5.7: Jump to the lower end of the disk

Step 5.8: Traverse the disk request array from the lower end towards the start

Step 5.9: Calculate the seek time as the absolute difference between the current request and the previous request

Step 5.10: Update the current head position to the current request

Step 5.11: Repeat until reaching the start of the disk

Step 5.12: Display the sequence of disk access and the total seek time

Step 6: Display the function LOOK

Step 6.1: Sort the disk request array in ascending order

Step 6.2: Find the index where the head is located

Step 6.3: Traverse the disk request array from the head position towards higher cylinder number

Step 6.4: Calculate the seek time as the absolute difference between the current request and the previous request

Step 6.5: Update the current head position to the current request

Step 6.6: Repeat until reaching the end of the disk or no further requests are available in that direction

Step 6.7: Jump to the lower end of the disk

Step 6.8: Traverse the disk request array from the lower end towards the start

Step 6.9: Calculate the seek time as the absolute difference between the current request and the previous request

Step 6.10: Update the current head position to the current request

Step 6.11: Repeat until reaching the start of the disk or no further requests are available in that direction

Step 6.12: Display the sequence of disk access and the total seek time

Step 7: Display the function C-LOOK

Step 7.1: Sort the disk request array in ascending order

Step 7.2: Find the index where the head is located

Step 7.3: Traverse the disk request array from the head position towards higher cylinder number

Step 7.4: Calculate the seek time as the absolute difference between the current request and the previous request

Step 7.5: Update the current head position to the current request

Step 7.6: Repeat until reaching the end of the disk or no further requests are available in that direction

Step 7.7: Traverse the disk request array from the lower end towards the start

Step 7.8: Calculate the seek time as the absolute difference between the current request and the previous request

Step 7.9: Update the current head position to the current request

Step 7.10: Repeat until reaching the start of the disk or no further requests are available in that direction

Step 7.11: Display the sequence of disk access and total seek time

Step 8: Call the function fcfs (), sstf(), scan(), cscan(), look(), clook()

Step 9: Stop

PROGRAM:

```
#include <stdio.h>
#include <stdlib.h>
#include <limits.h>
void fcfs(int disk[], int n, int head) {
    int i, seek_time = 0;
    printf("\nFCFS Scheduling:\n");
    printf("Sequence of disk access:");
    for (i = 0; i < n; i++) {
        printf(" %d", disk[i]);
        seek_time += abs(disk[i] - head);
        head = disk[i];
    }

Total Seek Time: 329

LOOK Scheduling:
Sequence of disk access: 14 37 65 67 98 122 124 183
Total Seek Time: 178

LOOK Scheduling:
Sequence of disk access: 14
Total Seek Time: 9

```

RESULT:

Thus, the c program to implement various disk scheduling algorithms was executed successfully.

EX NO:16

INSTALL ANY GUEST OPERATING SYSTEM LIKE LINUX USING VMWARE

DATE:

AIM:

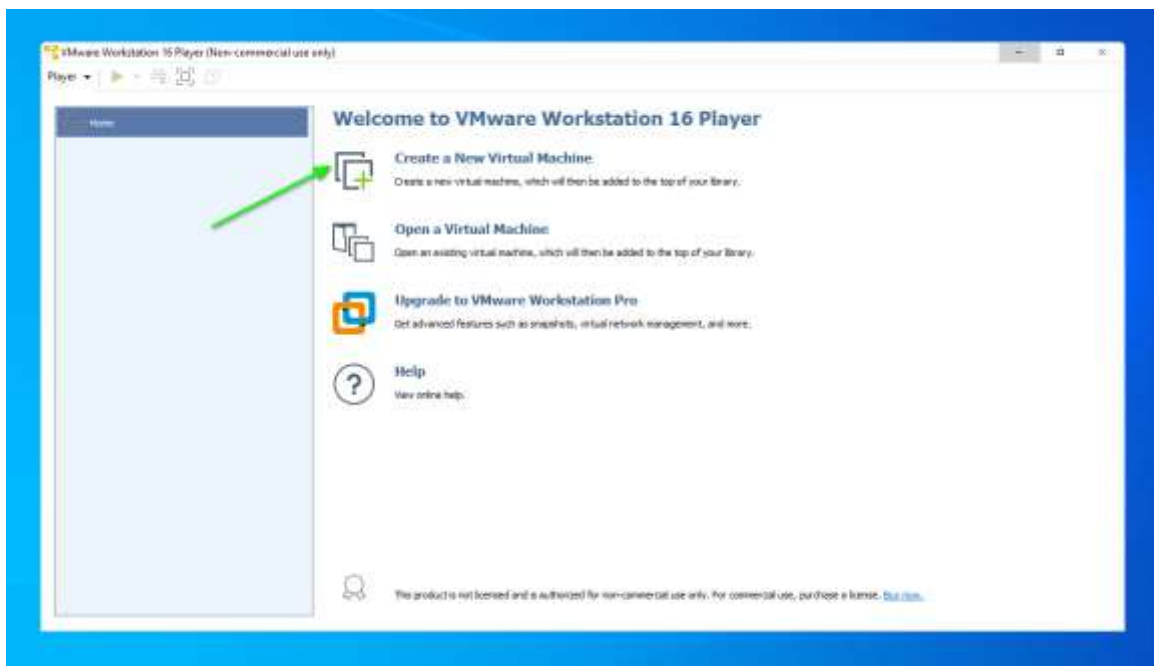

To Install Any Guest Operating System Like Linux Using VMWare

PROCEDURE:

Step 1: Install VMware: Download and install VMware Workstation or VMware Player on your host operating system (the system on which VMware will be installed).

Step 2: Obtain the Linux ISO: Download the ISO file for the Linux distribution you want to install as the guest operating system. You can obtain the ISO file from the official website of the Linux distribution or from trusted sources.

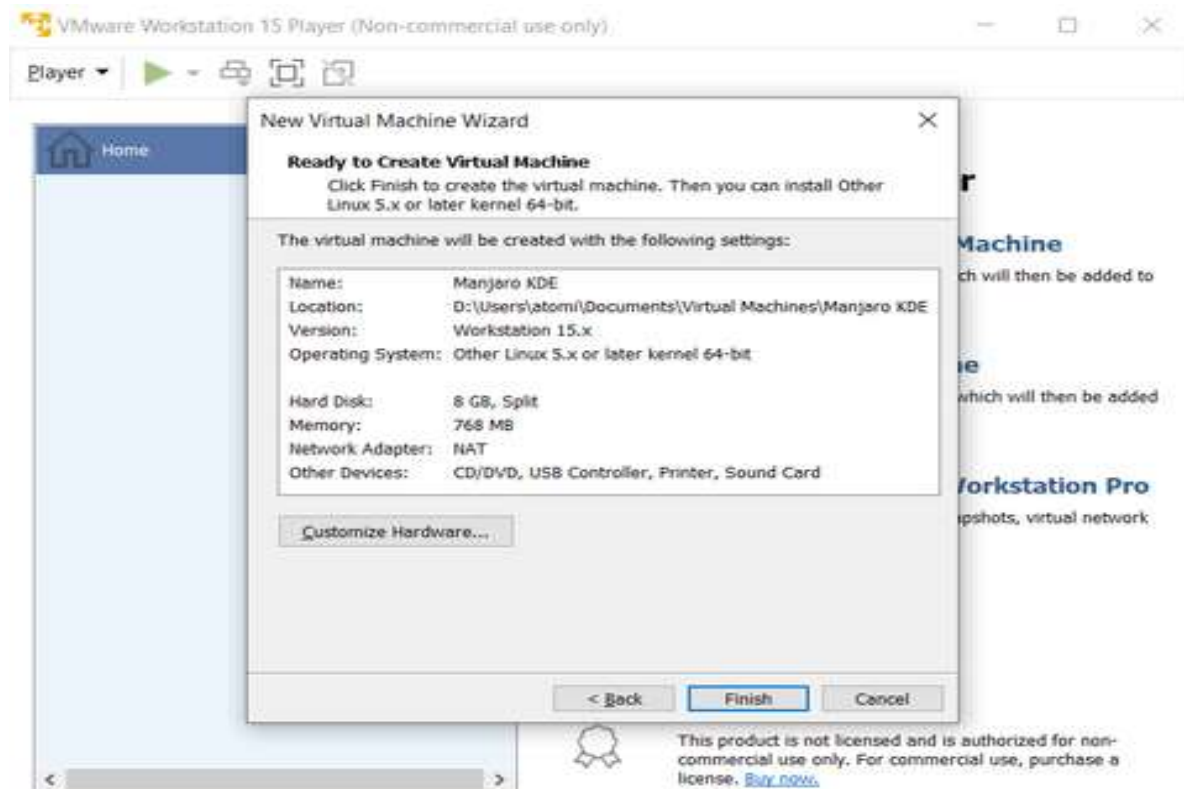

Step 3: Open VMware: Launch the VMware application on your host operating system.

Step 4: Create a new virtual machine: Click on the "Create a New Virtual Machine" or "New Virtual Machine" option in the VMware application to start the virtual machine creation wizard.

Step 5: Select the installation method: Choose the option to install the guest operating system from an ISO image. Browse and select the Linux ISO file you downloaded in step 2.

Step 6: Specify guest operating system details: Select the appropriate Linux distribution and version from the list provided by VMware. If your Linux distribution is not listed, choose the closest match or select "Other Linux."

Step 7: Configure virtual machine settings: Specify the virtual machine name, location to store the virtual machine files, and allocate the desired amount of memory, CPU cores, and disk space for the virtual machine. Follow the recommended system requirements for the Linux distribution.

Step 8: Customize hardware settings (optional): You can customize additional hardware settings such as network adapters, graphics, sound, and other devices based on your requirements.

Step 9: Start the virtual machine: Once the virtual machine is created, select it from the VMware application and click on the "Play" or "Start" button to power on the virtual machine.

Step 10: Install Linux: The virtual machine will boot from the Linux ISO image. Follow the on-screen instructions to install Linux as you would on a physical machine. You may need to partition the virtual disk, select installation options, set up user accounts, and configure network settings.

Step 11: Complete the installation: Once the installation is finished, the virtual machine will restart. Log in to the Linux guest operating system using the credentials you set installation Process.

Step 12: Install VMware Tools (optional): VMware Tools provides enhanced performance and features for the guest operating system. Install VMware Tools within the Linux guest operating system to enable features like shared folders, drag and drop, and improved graphics.

RESULT:

Thus, the installation of Linux guest operating system using VM Ware was completed successfully
